Let's do a problem

- Use 20 counters.
- Create three groups as equal as you can.
- Could they have been all equal?

Let's do a problem

- Try again with 24 counters.

What did I get out of this?

- The idea that some numbers can be constructed into equal groups of a given size and some cannot.

Let's do another problem

- Use 24 counters to make two groups, but one group is a double of the other (It's like 2 of them put together.)

What did I get out of this?

- The idea that you could have just put together two of your three equal groups to get a group and its double ($x + 2x = 3x$).

Let's do a third problem

- Use 20 counters to create three groups.
- One group has to be super big and the other two have to be little.

What did I get out of this?

- You can ALWAYS decompose a number 3 or greater into three parts and if the number is past 10, you could always have a big part and two little parts.
- The big part is almost all of the number.

What contenu was I addressing?

- 2^e année:

utiliser du matériel de manipulation pour composer et décomposer des nombres (p. ex., 42 peut être représenté par 4 groupes de 10 et 2 unités, par 3 groupes de 10 et 12 unités).

But I put “meat” on the contenus

I was addressing what I will call essential understandings.

Teachers need to borrow or learn about them so they don't just “do stuff”.

I would argue

- That just “doing” content is not enough to lead to mathematical success.
- Students need to meet ideas and not just solve random problems.

Valuable work

- Would be to look at content and think about what ideas need to be addressed.
- Teachers should be expected to be able to articulate what those ideas are.

Let's try one together

- What ideas are embedded in this content?

1^e année

compter au moins jusqu'à 60 par 1 et par intervalles de 2, de 5 et de 10, avec ou sans matériel concret à partir des nombres respectifs 1, 2, 5 et 10 (p. ex., abaque, grille de 100, droite numérique).

For me, it might be these ideas:

You skip numbers when you don't count by 1s, and there is a pattern to how you skip.

For example, if you skip count by 2s, you start and skip a number you say the next one.

But if you skip count by 5s, you start and skip 4 numbers before you say the next one.

If you skip count by a bigger number, you get higher faster.

For example, 20 is the second number in 10, 20,... but the 10th in 2, 4, 6, 8,...

3^e année

- représenter les demis et les quarts en tant que parties d'un élément et d'un ensemble d'éléments à l'aide de matériel concret (p. ex., horloge).

- A fourth is always half of a half, so if you have a half, you can construct a fourth.

If you have a fourth, you can construct a half, by using two of them.

- A half can be a lot or a little. So can a fourth.

So now...

Choose a contenu in number in your grade.

Think about what ideas you would want to come out.

So is there a list of essential understandings?

Yes and no.

I have various lists in different books I have written or am writing, but they are not everybody's.

How does it play for me when teaching?

The first place is in setting learning goals for the lesson.

The second is in choosing activities to lead me to those goals.

How does it play for me when teaching?

The third is in consolidation.

The fourth is in assessment of learning.

Setting Learning Goals

Here are examples of learning goals I have set to fit 1^e année contenus.

Setting Learning Goals

- choisir une unité de mesure non conventionnelle appropriée pour mesurer une longueur donnée (p. ex., soulier, ficelle, trombone).

Setting Learning Goals

- My goal might be that students realize that an appropriate unit changes depending on purpose.

Setting Learning Goals

décrire la position d'un objet par rapport à un autre en utilisant les termes : *sur, sous, à gauche, à droite, à côté, devant, derrière, au-dessus, en dessous, entre, en haut, en bas.*

My learning goal might be that often these words come in pairs and if you use one word to describe how two objects are positioned, you could have said the same thing using another word.

2^e année

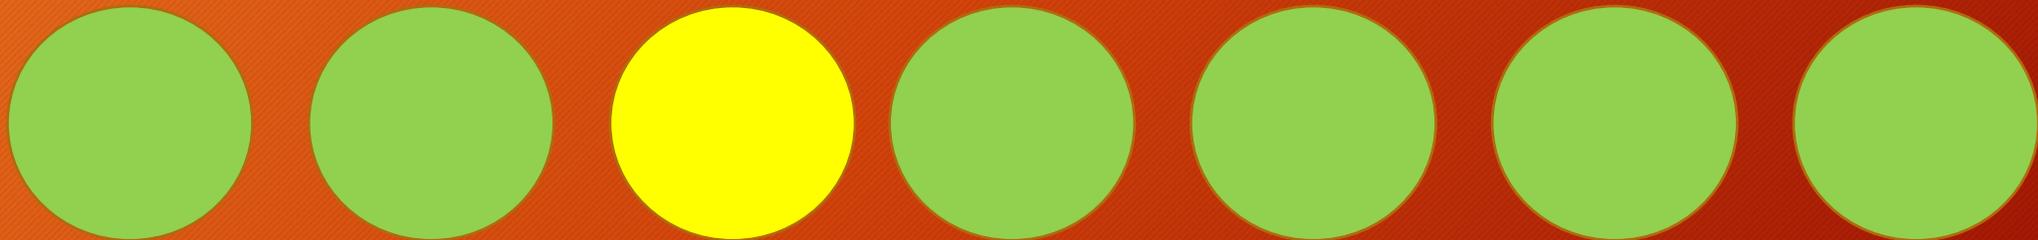

utiliser les nombres ordinaux jusqu'à 50 (p. ex., c'est aujourd'hui la quarante-deuxième journée d'école depuis la rentrée scolaire).

2^e année

My learning goal might be that ordinal numbers can change depending on perspective.

2^e année

For example, the yellow circle could be 3rd or 5th depending where you are looking from.

2^e année

classer et classifier des figures planes selon des propriétés (p. ex., nombre de côtés, nombre de sommets) dans le but de les identifier, de les comparer et de les décrire.

2^e année

My learning goal might be that students realize that two objects might belong together for some reason, but the same two objects might also not belong together if you consider a different attribute.

2^e année

For example, a carrot and a banana go together if you are putting together things that you eat, but they do not go together if you are considering which is a fruit.

3^e année

- estimer une quantité d'objets jusqu'à 1 000.

3^e année

My learning goal might be that it is easier to estimate if you have a “related” benchmark that you know the quantity of.

3^e année

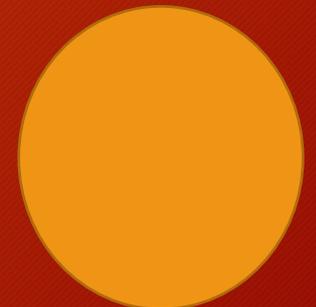

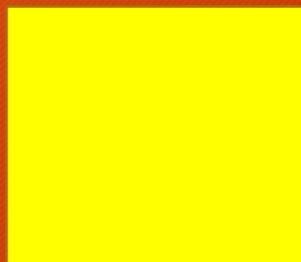

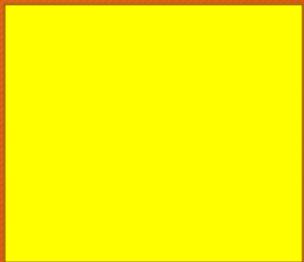

- créer une suite non numérique à motif répété et à motif croissant, à l'aide d'au moins deux attributs (p. ex., taille, couleur, position [translation, réflexion]).

3^e année

My learning goal might be that sometimes patterns repeat based on two attributes in the same way, but sometimes in different ways.

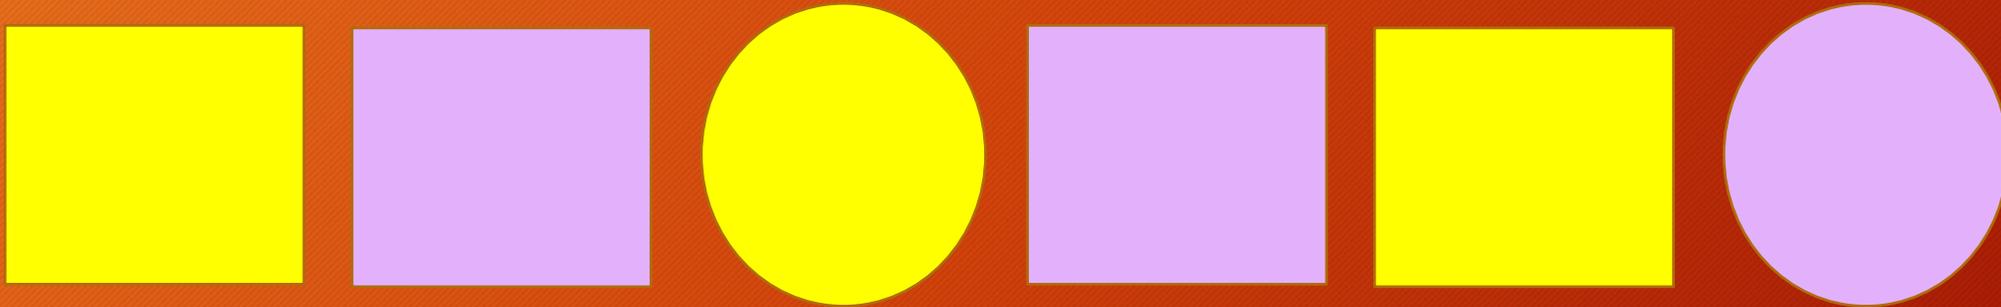

3^e année

For example, this is an AB pattern in both colour and shape.

3^e année

But this is AB in colour, but AAB in shape.

Your turn

Each team needs to choose one or two contents that you might address by being much more clear about a learning goal which is about an IDEA (not skill) that you want students to learn.

Choosing activities to lead to a learning goal

Once I have a goal, it should make it easier to choose an appropriate activity.

For example...

My learning goal in Grade 1 might be that students realize that an equation describes a balance.

For example...

The activity:

- Use 2 different colours of cubes on one side of the balance.
- Use 2 other colours of cubes on the other side of the balance.
- Make sure there is a balance.

For example...

- Write an addition equation that describes the balance.
- Repeat with other amounts of cubes.

Then I consolidate..

- I post some of the equations students have created and ask kids to notice things.

Then I consolidate..

- I ask:

If you lined up all the cubes on the left and then all the cubes on the right, what would happen?

Then I consolidate..

- I ask :
- Suppose one side had 6 red and some yellow.
- The other side had 8 blue and some green.
- Were there more yellow or green? How do you know?

Then I consolidate..

- I ask :
- Suppose one side had 3 red and some yellow.
- The other side had 1 blue and some green.
- Were there more yellow or green? How do you know?

Then I consolidate..

- I ask :
- Why were your equations addition equations?

Notice

My consolidation focused on my learning goal.

It could be 2^e année

My learning goal might be that students realize that knowing you can usually represent two-digit numbers as tens and ones in many ways.

It could be 2^e année

My activity might be to provide base ten rods and ones.

I ask them to accomplish these tasks:

It could be 2^e année

- Represent 23 with 5 blocks.
- Represent 23 with 23 blocks.
- Represent 23 with a different number of blocks.

It could be 2^e année

- Represent 65 with blocks at least 3 ways.
- Represent a number with 12 blocks. Now represent it with a different number of blocks.

Consolidation

- I might ask:
 - You represented 23 with 5 blocks.
What 2-digit number could you have represented with 6 blocks?

Consolidation

- I might ask:
 - Did anyone use 20 blocks to represent 65? How could you do that?
 - How could you have used more blocks?

Consolidation

- I might ask:
 - What number did you represent with 12 blocks?
 - What other amounts of blocks could you have used for that number?

It could be 3^e année

My learning goal might be that students realize that you can represent an amount of money in different ways and that it takes more bills and coins if they are of lower value.

It could be 3^e année

I might set a task like this.

Choose an amount of money between
\$20 and \$30.

It could be 3^e année

Represent it using a LOT of bills or coins.

Then represent it using NOT MANY bills or coins.

It could be 3^e année

Repeat with one other amount of money.

Consolidation

My questions:

- Who thinks they represented their amount using fewer pieces of money than anyone else in the room? Why do you think it could be you?

Consolidation

My questions:

- Who thinks they represented their amount using one of the most pieces of money in the room? Why do you think it could be you?

Consolidation

- Suppose you had used only dimes. Would you use a lot of coins or not many?
- Suppose you had used a \$20 bill. Could you still have used a lot of pieces of money?

Consolidation

- When do you use a lot of pieces of money?
When don't you?

Your turn

- You come up with the questions for this activity.
- My learning goal is that students realize that you can sometimes decide which number is greater using close by numbers you already know how to compare OR The ones digit doesn't matter nearly as much as the tens digit when you are comparing numbers.

Your turn

- Spin to get the rest of these numbers:
- 6[] []1 []5
-
- Now find a few numbers that are:

Your turn

- - less than all of them 6[] []1 []5
- - more than all of them
- - more than only one of them
- - between the first two
- - between the last two

Your turn

- You come up with the consolidation questions for this activity.

Some ideas I had

- Was it easier to choose numbers lower than 6[] or higher than 6[]? Explain.
-
- Why was your number less than all of them never in the 70s?

Some ideas I had

- Why was your number more than all of them never in the 50s?
-
- What strategy did you use to figure out a number more than only one of them?

Learning Goals

- When you make a design with symmetry, there can be an odd number of shapes or an even number.
- It depends on whether there is a shape ON the line of symmetry.

Getting ready

Which two shapes do you think are most alike? Why those two?

Main activity

Make a pattern block design that follows these rules.

- There is symmetry.
- There are 4 more yellow blocks than blue ones.
- There are as many blue as red blocks.

How do you know there is symmetry?

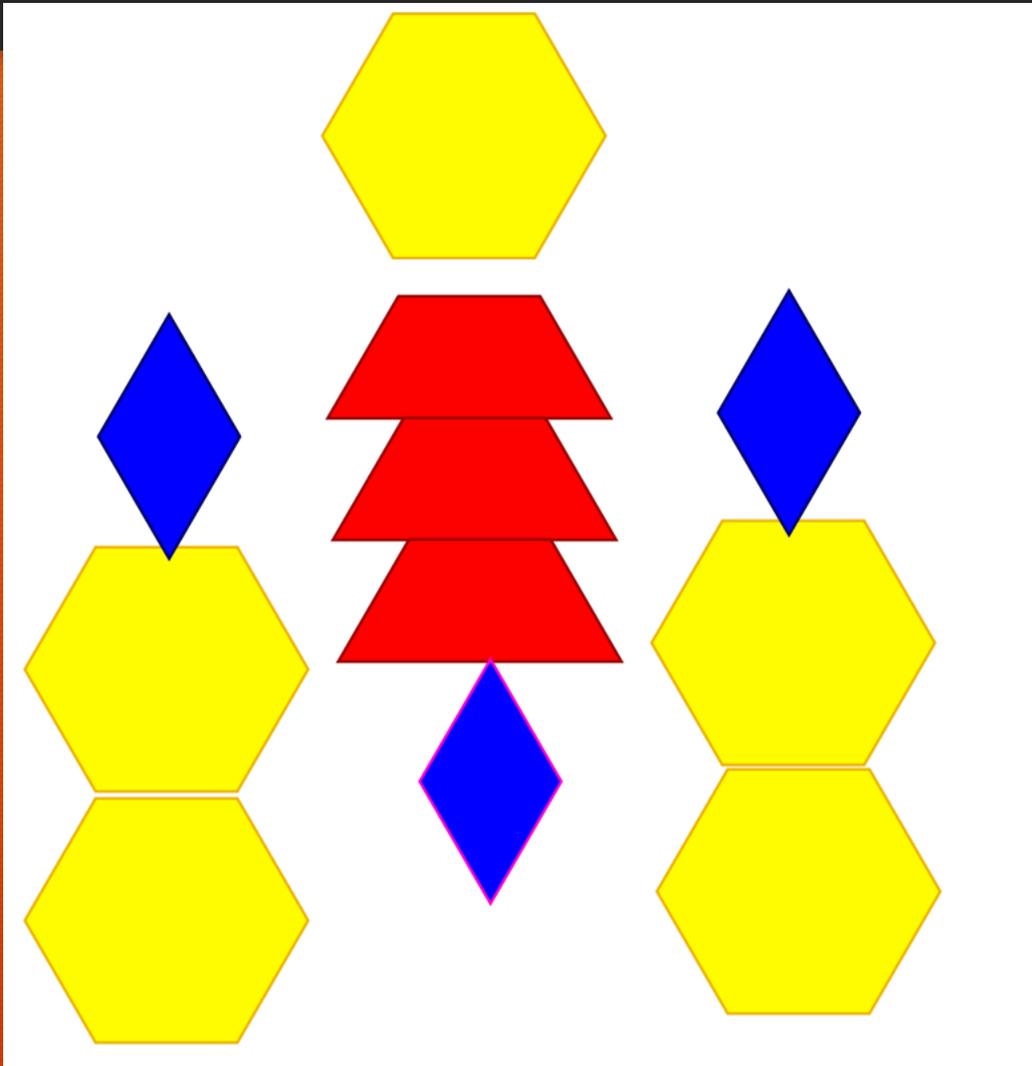

Possible design

Make a pattern block design that follows these rules.

- There is symmetry.
- There are 2 more yellow blocks than blue ones.
- There are as many blue as red blocks.

How do you know there is symmetry?

Possible design

consolidation

What questions can I ask?

consolidation

- How can you look at a design and know it does not have symmetry?
- Can a design made of 2 shapes have symmetry?
How?

consolidation

- Can a design made of 3 shapes have symmetry?
How?
- If there are only two yellow blocks in the design and one is far to the right, where is the other?
How do you know?

Assessment

Assessment needs to match instruction.

Teaching with intention means assessing with intention.

Assessment

If your goal for your students in math is just “doing it”, you will have mostly knowledge items with some application thrown in.

Assessment

But if your goal is to build math thinkers, you will focus much more on understanding and thinking questions.

For example

Instead of: Which is greater? 49 or 76

You might ask: Which number is probably greater? Why?

4[] OR []6

For example

Instead of: What combinations of numbers add to 10?

You would ask: How can using a ten-frame make it easy to figure out numbers that add to 10?

For example

Instead of: Estimate $38 + 45$.

You would ask: Why might someone estimate 70?

Why might someone else estimate 80?

Would 90 also be a good estimate?

For example

Instead of: What time does the clock show?
You would ask: If a clock could only have one hand, would you choose the minute hand or the hour hand? Why?

For example

Instead of giving a problem for students to solve,

You would ask: What problem might have led you to figure out $100 - 27$ to solve it?

Today

Was a lot of hard thinking.

You can't change overnight, but maybe choose something you heard today that you are ready to work on.
